## Basilar membrane

The **basilar membrane** stretches from the tympanic lip of the osseous spiral lamina to the basilar crest and consists of two parts. The inner is thin, and is named the **pars arcuata**. The outer is thicker and striated, and is termed the **pars pectinata**. The under surface of the membrane is covered by a layer of vascular connective tissue; one of the vessels in this tissue is somewhat larger than the rest, and is named the **vas spirale**; it lies below Corti's tunnel.

162 L. M. Cabezudo

Fig. 2. Schematic drawing showing the variation in thickness of the basilar membrane along the cochlear duct at six different points in the same cat. The black and shaded portions represent the outline of the homogeneous ground substance with the filaments included and the area occu-

pied by the mesothelial cells, respectively. The vertical axis corresponds to the distance from the base in mm. In each case the arrow on the right side indicates the basilar crest and the left arrow indicates the demarkation between the pars tecta and the pars pectinata.

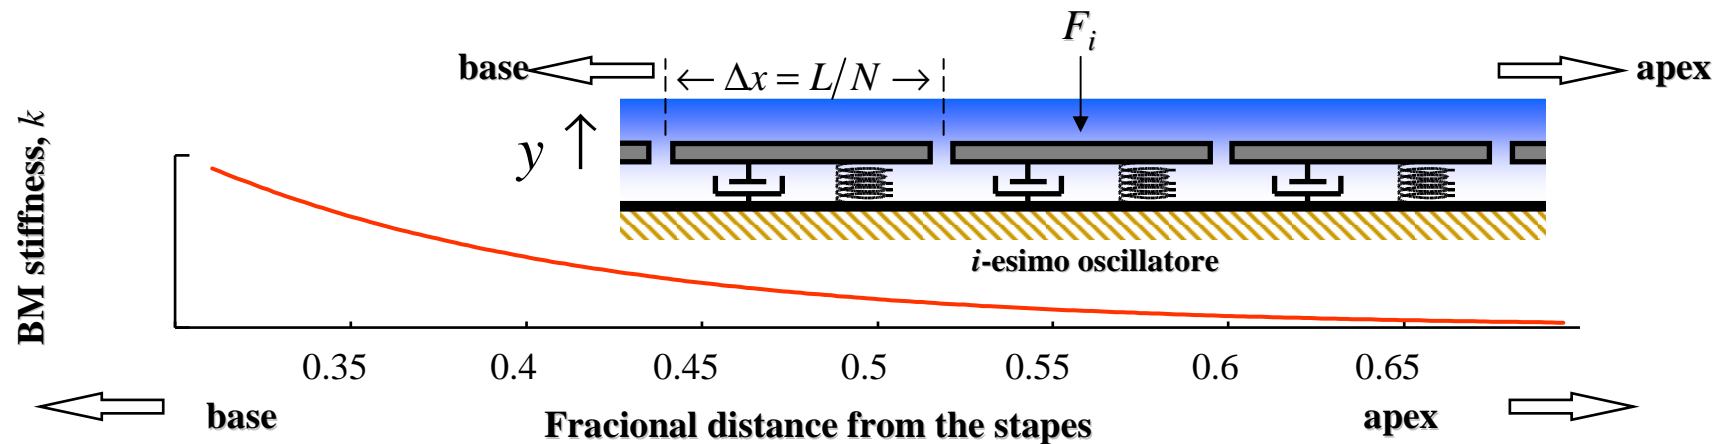

## A mechanical model for the basilar membrane

The elastic basilar membrane supports the spiral organ of Corti that, in humans, can be subdivided into approximately  $N = 3600$  transversal segments.

The  $i$ -th segment may be further schematized as a damped harmonic oscillator driven by **fluid pressure forces**

$$m_i a_i + h_i v_i + k_i y_i = F_i$$

Motion equation for the  $i$ -th oscillator driven by the force  $F_i$

**Resonance curves**

Au plus près de la cochlée

To compute the forces  $F_i$ , we need to know how the fluid moves within the cochlea

Fluid motion is driven by the piston action of the stapes bone in the oval window.

### Known parameters:

$u$  (max fluid velocity)  $\sim 4.5 \times 10^{-3} \text{ m s}^{-1}$  [T.Ren, a 90 dB SPL]

$\eta$  (viscosity)  $\sim 1.5 \text{ kg m}^{-1} \text{ s}^{-1}$  [von Békésy]

$\rho$  (density)  $\sim 1000 \text{ kg m}^{-3}$  [water]

$D$  (pipe diameter)  $\sim 1 \text{ mm} = 10^{-3} \text{ m}$  [on average]

$N_R > 2000$

Reynolds number  $N_R = \frac{\rho v D}{\eta} \approx \frac{(1000) (4.5 \times 10^{-3}) (10^{-3})}{1.5 \times 10^{-3}} = 3$

**The small value of  $N_R$  guarantees that fluid motion is laminar**

## Fluid pressure forces due to the acceleration of the stapes

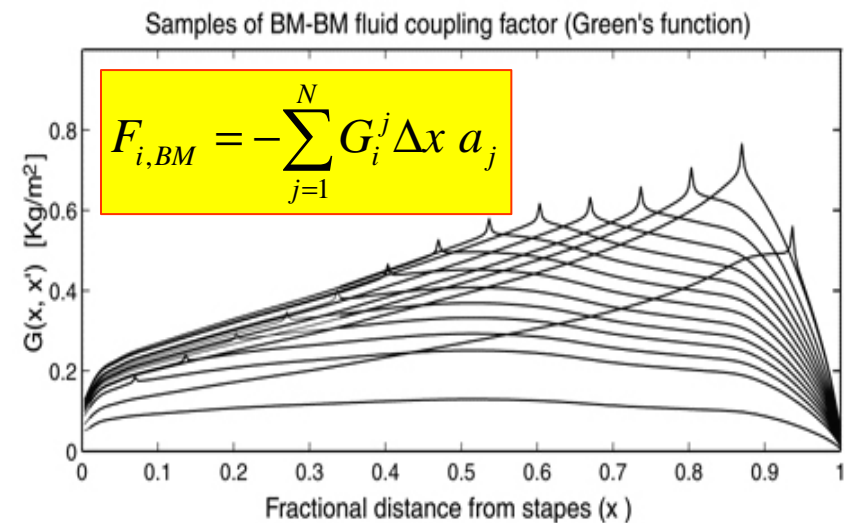

Plot of the stapes-BM coupling factor for the **human cochlea**.

## Additional pressure forces are generated by the basilar membrane reaction

Each segment of the basilar membrane that is set into motion by the pressure field generated by the stapes generates an additional pressure field.

While moving e.g. downward, the segment must displace the surrounding fluid **instantaneously generating pressure forces in the opposite (upward) direction** on all other basilar membrane segments.

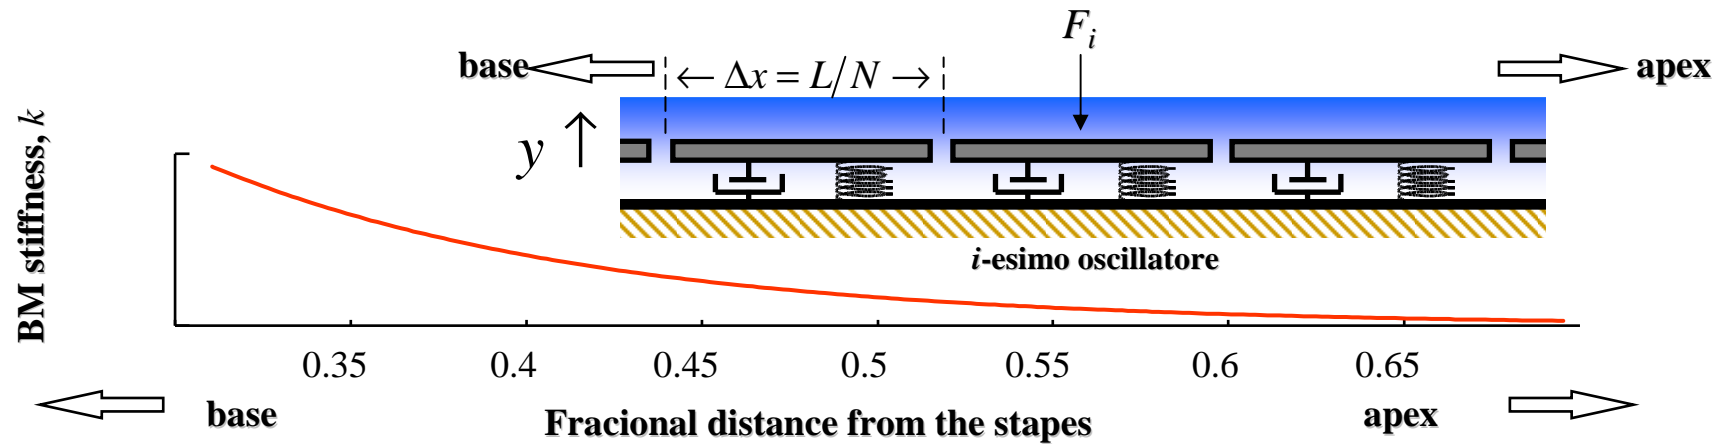

The **diagonal terms**  $G_i^i$  represent the inertial reaction of fluid mass that the  $i$ -th moving segment of the basilar membrane must displace. The situation is similar to that of a piston in a closed fluid circuit.

$$m_i a_i + h_i v_i + k_i y_i = F_i$$

Motion equation for the  $i$ -th oscillator driven by the force  $F_i$

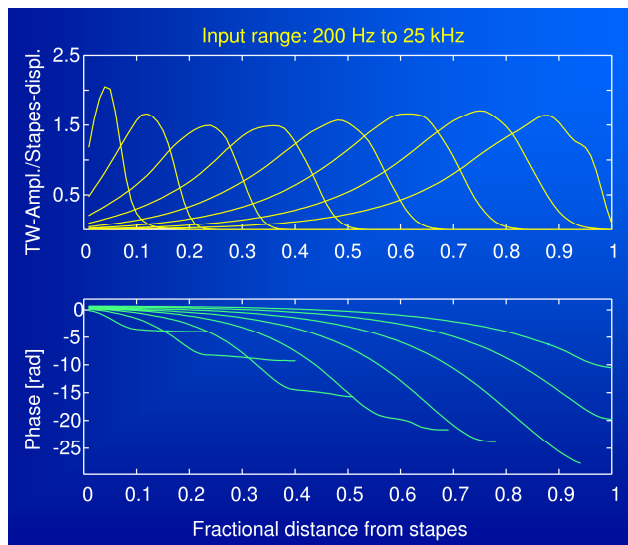

$$F_i = -G_{i,S} a_S - \sum_{j=1}^N G_i^j \Delta x a_j$$
